## Introduction

This document assists the designer of a control system in choosing an Allen-Bradley Molded Case Circuit Breaker (MCCB) or Miniature Circuit Breaker (MCB) for proper coordination in main (primary) and branch circuits. You can choose either Selective Protection or Back-up Protection based on these tables in this publication. The values represent the maximum current [kA], and breaking capacity according to IEC 60947-2 applied for 400/415V AC systems. The 480V/600V table values are represented as Interrupting Ratings, which conform to UL 489/CSA22.2, No. 5 standards.

A proper selection of protection system helps to maintain safe and economical function of electrical installation and can reduce losses that are associated with unwanted service interruptions.

NEC (2014), Article 100 defines selective coordination as “Localization of an overcurrent condition to restrict outages to the circuit or equipment affected, accomplished by the selection and installation of overcurrent protective devices and their ratings or settings for the full range of available overcurrents, from overload to the maximum available fault current, and for the full range of overcurrent protective device opening times associated with those overcurrents.”

Trip selectivity (for overcurrent) is defined in EN/IEC 60947-1 (2.5.23) as coordination between the operating characteristics of two or more overcurrent protection devices, so that when an overcurrent within established limits occurs, the device destined to operate within those limits trips whereas the others do not trip.

Time/current characteristics of circuit breakers determine the time that it takes to clear the fault for a given value of fault current. Any fault on a branch circuit should open the branch-circuit breaker rather than the feeder overcurrent protection.

In an electrical system with selective coordination of protective devices, the fault is isolated and cleared by the nearest upstream breaker, while the rest of the system stays operational.

In a system with a back-up protection (series-rated), an upstream device in the series operates and limits the current to protect a downstream device.

Typical applications that require selective coordination could include emergency systems and standby backup, and critical manufacturing processes.

## Selectivity

The definitions of total selectivity and partial selectivity are given in Part 2 of the same Standard: IEC 60947-2 “Low voltage Equipment - Part 2: Circuit-breakers”.

Total selectivity is defined in EN/IEC 60947-1 (2.17.2) as “overcurrent selectivity where, in the presence of two protection devices against overcurrent in series, the load- side protection device carries out the protection without making the other device trip.”

Partial selectivity is defined in EN/IEC 60947-1 (2.17.3) as “overcurrent selectivity where, in the presence of two protection devices against overcurrent in series, the load- side protection device carries out the protection up to a given level of overcurrent, without making the other device trip”.

This overcurrent threshold is called the “Selectivity limit current  $I_s$ .

Selectivity limit current,  $I_s$ , is defined in EN/IEC 60947-1 (4.2) as “the current co-ordinate of the intersection between the total time-current characteristic of the protective device on the load side and the tripping time-current characteristic of the other protective device.” The selectivity limit current is a limiting value of current.

- below which, in the presence of two overcurrent protective devices in series, the protective device on the load side completes its breaking operation in time to prevent the other protective device from starting its operation (selectivity is ensured);
- above which, in the presence of two overcurrent protective devices in series, the protective device on the load side may not complete its breaking operation in time to prevent the other protective device from starting its operation (selectivity is not ensured).

In other words, total selectivity is achieved when there is a selectivity at any possible value of overcurrent, up to the lowest  $I_{cu}$  of installed circuit breakers in a system.

A partial selectivity is achieved when circuit breakers are coordinated up to a certain  $I_s$  current value. When the current exceeds this value, selectivity between the two circuit breakers is no longer guaranteed. However, if the maximum prospective short-circuit current of the installation is lower than or equal to the  $I_s$  selectivity value, such system will have total selectivity.

## Additional Current Definitions

Throughout this publication, we refer to a number of additional types of current. The following list explains these current ratings.

- $I_s$  — selectivity limit current: the current co-ordinate of the intersection between the total time-current characteristic of the protective device on the load side and the tripping time-current characteristic of the other protective device.
- $I_{cu}$  — ultimate breaking capacity: the maximum short-circuit current that a circuit breaker can break without damage.

- $I_{cs}$  — service breaking capacity: expressed as a percentage ratio of  $I_{cu}$  and tells you the maximum short-circuit current if a circuit breaker can break three times and still resume normal service.
- $I_n$  — rated current: the value of current that characterizes the protection release that is installed on board the circuit-breaker and determines, based on the settings available for the release, the protective characteristic of the circuit-breaker itself.

## How to Interpret the Selectivity Tables

### Example 1—Total Selectivity

For this example, we will consider a selectivity study between two circuit breakers: 140G-J, 90 A and 1492-SPM, 8 A ([Figure 1](#)).

**Figure 1 - Selectivity Between Line Side 140G-J 90 A and Load Side 1492-SPM 8 A Circuit Breakers**

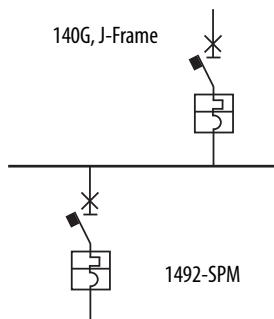

Table Legend: Numerical Values = Selectivity Limit [kA] T= Total Selectivity (for definitions, see <a href="#">page 2</a> )			Line Side - 415V Incoming									
			Breaker Type: 140G J-Frame Molded Case Circuit Breaker									
			Ultimate Breaking Capacity $I_{cu}$ [kA] = 36, 50, 70, 120									
			Thermal-magnetic Trip									
Load Side			Rated Current $I_n$ [A]									
Breaker Type	Ultimate Breaking Capacity $I_{cu}$ [kA]	Rated Current $I_n$ [A]	25	30	35	40	50	60	70	80	90	100
Bulletin 1492-SPM Miniature Circuit Breaker	0.5...4	T	T	T	T	T	T	T	T	T	T	T
	6	—	6	6	7.5	10	10	T	T	T	T	T
	8	—	—	—	6	7.5	10	10	T	T	T	T
	10	—	—	—	6.5	7.5	7.5	—	—	9	T	T
	13	—	—	—	—	—	—	7.5	8	8	T	T
	16	—	—	—	—	—	—	—	8	8	T	T
	20	—	—	—	—	—	—	—	—	—	—	T

From the coordination tables, we can determine that there is total selectivity (T) between the two circuit breakers.

This means that there is selectivity up to 15 kA, the lower of the two  $I_{cu}$  values. The maximum possible short-circuit current at the point of installation of the 1492-SPM 8A circuit breaker will be less than or equal to 15 kA.

### Example 2—Partial Selectivity

**Figure 2 - Selectivity Between 140G-J 60 A and 1492-SPM 8 A Circuit Breakers**

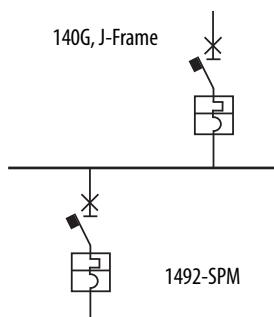

Table Legend: Numerical Values = Selectivity Limit [kA] T= Total Selectivity (for definitions, see <a href="#">page 2</a> )			Line Side - 415V Incoming									
			Breaker Type: 140G J-Frame Molded Case Circuit Breaker									
			Ultimate Breaking Capacity $I_{cu}$ [kA] = 36, 50, 70, 120									
			Thermal-magnetic Trip									
Breaker Type	Ultimate Breaking Capacity $I_{cu}$ [kA]	Rated Current $I_n$ [A]	25	30	35	40	50	60	70	80	90	100
Bulletin 1492-SPM Miniature Circuit Breaker	0.5...4	T	T	T	T	T	T	T	T	T	T	T
	6	—	6	6	7.5	10	10	T	T	T	T	T
	8	—	—	—	6	7.5	10	10	T	T	T	T
	10	—	—	—	—	6.5	7.5	7.5	—	9	9	T
	13	—	—	—	—	—	—	7.5	8	8	T	T
	16	—	—	—	—	—	—	—	8	8	T	T
	20	—	—	—	—	—	—	—	—	—	—	T

In this example ([Figure 2](#)), we consider a 60 A 140G-J breaker. From the coordination table, the selectivity value,  $I_s$ , is 10 kA between the two circuit breakers. This means that if the maximum prospective short-circuit current on the load side of the 1492-SPM 8A circuit breaker is less than 10 kA, there will be total selectivity. If the short-circuit current has a value between 10 kA and 15 kA, there will be partial selectivity. This means that the supply breaker may trip.

## Back-up Protection

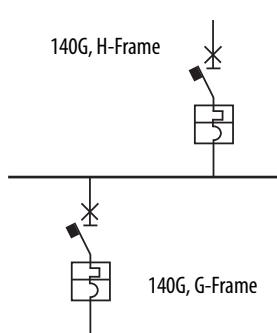

Back-up protection is defined in EN/IEC60947-1, 2.5.24 as “Over-current coordination of two overcurrent protective devices in series where the protective device, generally but not necessarily on the supply side, effects the overcurrent protection with or without the assistance of the other protective device and prevents any excessive stress on the latter.”

In a system with a back-up protection (series-rated), an upstream device in the series will operate and limit the current to protect a downstream device. The supply side circuit breaker will limit the current (and total energy) to allow load side devices to interrupt short-circuit currents beyond their breaking capacity. In this case both devices (placed in series) may open simultaneously, alternatively, or just the supply side circuit breaker. Our tables are derived from tests based on appendix A of the IEC60947-2 Standard.

## How to Interpret the Back-up Protection Tables

You should interpret the back-up protection in the same way as you interpret selectivity tables.

### Example 3

**Figure 3 - Two 140G Molded Case Circuit Breakers Installed in Series****Table 30 - Line Side 140G MCCB, Load Side, Load Side 140G MCCB**

<b>Table Legend:</b> Numerical Values = Selectivity Limit $[kA]$ $T$ = Total Selectivity (for definitions, see <a href="#">page 2</a> )		Line Side - 415V Incoming												
		Ultimate Breaking Capacity $I_{cu}$ [kA]												
		50						70						
		Bul. 140G MCCB Frame Size						Bul. 140G MCCB Frame Size						
Ultimate Breaking Capacity $I_{cu}$ [kA]	Bul. 140G MCCB Frame Size	G	H	I	J	K	M	N	G	H	J	K	M	N
50	G	—	—	—	—	—	—	—	70	70	70	70	70	70
	H	—	—	—	—	—	—	—	—	70	70	70	70	70
	I	—	—	—	—	—	—	—	—	70	70	70	70	—
	J	—	—	—	—	—	—	—	—	70	70	70	70	70
	K	—	—	—	—	—	—	—	—	—	70	70	70	70

In this example, ([Figure 3](#)), two 140G MCCBs are installed in series. The 140G-G circuit breaker has an  $I_{cu}$  rating of 50 kA and the 140G-H breaker has an  $I_{cu}$  of 70 kA, so this complete installation is rated up to 70 kA @ 415V.
